

- 1) Let's say that x^5 is $O(n^2)$. If this is true, then there exists positive constants $c > n_0$ such that for all $n \geq n_0$, $n^5 \leq cn^2$

$$\begin{aligned}n^5 &\leq cn^2 \\n^3 &\leq c\end{aligned}$$

This fails for n greater than c . Therefore we have a contradiction and x^5 is not $O(n^2)$.

2) $\sum_{i=1}^n i^3 = \frac{n^2(n+1)^2}{4} = \frac{n^2(n^2+2n+1)}{4} = \frac{n^4+2n^3+n^2}{4}$

By the definition of Big-O, the runtime is $\Theta(n^4)$ if and only if it's $O(n^4)$ and $\Omega(n^4)$.

Q Let $f(n) = \frac{n^4+2n^3+n^2}{4}$, $f(n) = O(g(n))$ iff $f(n) \leq cg(n)$ for all $n \geq n_0$, where C and n_0 are positive constants.

$$\frac{f(n)}{g(n)} \leq C \text{ for all } n \geq n_0$$

$$\frac{n^4+2n^3+n^2}{4} \leq cn^4$$

$$\frac{n^4}{4n^4} + \frac{2n^3}{4n^4} + \frac{n^2}{4n^4} \leq c$$

$$\frac{1}{4} + \frac{1}{2n} + \frac{1}{4n^2} \leq c$$

$$\frac{1}{4} + \frac{1}{2} + \frac{1}{4} \leq c \quad , \quad n_0 = 1$$

$$1 \leq c \quad \boxed{c=1, n_0=1}$$

2) $f(n) \geq cg(n)$ for all $n \geq n_0$ where $c > 0$ are positive constants.

$$\frac{f(n)}{g(n)} \geq c \text{ for all } n \geq n_0$$

$$\frac{n^4 + 2n^3 + n^2}{4} \geq cn^4$$

$$\frac{1}{4} + \frac{1}{2n_0} + \frac{1}{4n_0^2} \geq c$$

$$\frac{9}{16} \geq c, n_0 = 2$$

$$c = \frac{1}{4}, n_0 = 2$$

Thus, since $1^3 + 2^3 + 3^3 + \dots + n^3$ is shown to be $\Theta(n^4)$ and $\Omega(n^4)$, we can say it is $\Theta(n^4)$. QED.

3) $E_1 = 0$

$$E_k = E_{k-1} + k+1, k \geq 1$$

k

$$2 \quad E_1 + k+1$$

$$= 3$$

$$3 \quad E_2 + k+1$$

$$= 7$$

$$4 \quad E_3 + k+1$$

$$= 12$$

$$0, 3, (3+4), (3+4+5) + \dots + (3+4+\dots+k+k+1)$$

$$E_1 \quad E_2 \quad E_3 \quad E_4 \quad E_k$$

$$E_k = \frac{1}{2}k^2 + \frac{3}{2}k - 2$$

#4 we start with:

5	3	2	8	1	0	6	7	4
---	---	---	---	---	---	---	---	---

 $i=0$ (5), $j=8$ (4) and $k = \frac{0+8}{2} = 4$ (1).

we find that 4 is the median, and so we swap this with the 1st value

and we end up with

10	4	3	2	8	1	0	6	7	5
----	---	---	---	---	---	---	---	---	---

$p \downarrow$ $i \uparrow$ $\hookrightarrow x[i] < x[lo]$, perform swap

10	4	3	2	8	1	0	6	7	5
----	---	---	---	---	---	---	---	---	---

$p \downarrow$ $i \uparrow$ $\hookrightarrow x[i] < x[lo]$, perform swap

10	4	3	2	8	1	0	6	7	5
----	---	---	---	---	---	---	---	---	---

$p \downarrow$ $i \uparrow$ \hookrightarrow perform swap

10	4	3	2	8	1	0	6	7	5
----	---	---	---	---	---	---	---	---	---

$p \downarrow$ $i \uparrow$ \hookrightarrow no swap

10	4	3	2	1	8	0	6	7	5
----	---	---	---	---	---	---	---	---	---

10	4	3	2	1	0	8	6	7	5
----	---	---	---	---	---	---	---	---	---

$p \downarrow$ $i \uparrow$ \hookrightarrow no swap 2x

10	4	3	2	1	0	6	7	5
----	---	---	---	---	---	---	---	---

\hookrightarrow EXECUTE "swap(x[10], x[p])"

0	3	2	1	4	8	6	7	5
---	---	---	---	---	---	---	---	---

\hookrightarrow EXECUTE SECOND

qsort(x, p+1, hi)

$i=5$ (8), $j=8$ (5), $k = \frac{5+8}{2} = 7$ (7)

$i=0$ (6), $j=3$ (3), $k = \frac{3+7}{2} = 5$ (2)

We find 1 is median, swap w/ 1st value:

10	1	3	2	0
----	---	---	---	---

10	1	3	2	0
----	---	---	---	---

10	1	3	2	0

5a) E A D C G B F I H

5b) Swap first and last node.

Delete last node from heap.

Heapify.

A B C D E F G H I

6) Starting at the root of the heap, check left and right subtrees. For each subtree, if root value $\leq x$, then check left and right subtrees. It takes $O(k)$ time for this algorithm because it's impossible for there to be a key $> x$ in T to have a descendant that has a key $\leq x$.

~~7) Let the loop invariant be $I(n)$: sum product = a^n . The guard condition G of the while loop is $i \leq n$ or $i > n$. We will use the loop invariant theorem to prove that the while loop is correct with respect to the given pre- and post conditions.~~

8) invariant

0	4	1
1	4	a
2	4	$a+a$
3	4	$a+a+a$
4	4	$a+a+a+a$

pre-condition: $i=1, pow=1, i \leq n$

~~ex: $i=1, pow=1$~~

IH/loop invariant

~~BB:~~ pow = a^n

Base case: $n=0 \Rightarrow pow = a^0 = 1$

IS: Assume at the start of the k^{th} iteration, $pow = a^k$. At the start of the $(k+1)^{th}$ iteration, we will have $pow = pow * a$

$$= a^k * a = a^{k+1}$$

Termination: The loop terminates when $i=n$. When it ends, we are about to enter the $i=n+1$ iteration. By the loop invariant, when the loop ends, $pow = a^n$.

Page _____

#7.

Let the loop invariant be $I(n): xy + \text{product} = AB$

The guard condition G of the while loop is $[G: y \neq 0, \text{ or } y \neq 0]$

We will use the loop invariant theorem to prove that the while loop is correct with respect to the given pre and post conditions.

I. Basis property ($I(0)$) is true before the 1st iteration of the loop

$I(0)$ is $xy + \text{product} = AB$, where $x \neq 0$ and $y \neq 0$ because by the precondition, $x = A$, $y = B$ and A and B must be positive integers. Also by the precondition, $\text{product} = 0$. Since $xy + \text{product} = AB$ from the precondition is true before the first iteration of the loop, $I(0)$ is true.

II. Inductive property (If $G \wedge I(k)$ is true before a loop iteration (where $k \geq 0$), then $I(k+1)$ is true after the loop iteration)

Suppose k is a non-negative integer such that $G \wedge I(k)$ is true before an iteration of the loop. We will show that $I(k+1)$ is true after the loop iteration.

Since we know that G is true, $y_{\text{old}} \neq 0$ and we enter the loop. Before the execution of statement I, since we know $I(k)$ is true,

$$x_{\text{old}}y_{\text{old}} + \text{product}_{\text{old}} = AB, \text{ where } x_{\text{old}} \neq 0 \text{ and } y_{\text{old}} \neq 0$$

The execution of statement I has the following effect:

$$r_{\text{new}} = y_{\text{old}} \bmod 2, \text{ and by the quotient remainder theorem,}$$

$$y_{\text{old}} = 2q + r_{\text{new}}, \text{ where } q \in \mathbb{Z}, 0 \leq r_{\text{new}} < 2, 2q = k$$

If $r_{\text{new}} = 0$, then after the execution of the 1st if statement,

$$\begin{aligned} x_{\text{new}} &= 2x_{\text{old}} &\Rightarrow x_{\text{new}}y_{\text{new}} &= (2x_{\text{old}})\left(\frac{y_{\text{old}}}{2}\right) \\ y_{\text{new}} &= \frac{y_{\text{old}}}{2} && = x_{\text{old}}y_{\text{old}} \end{aligned}$$

$$\text{product}_{\text{new}} = \text{product}_{\text{old}}$$

$$\begin{aligned} x_{\text{new}}y_{\text{new}} + \text{product}_{\text{new}} &= x_{\text{old}}y_{\text{old}} + \text{product}_{\text{old}} \\ &= AB \end{aligned}$$

**MITCHELL CHAN R7Y9A
SANDRA YOO A9X9A**

If $x_{\text{new}} = 1$, knowing that $y_{\text{old}} = 2q + 1$, after execution of the first statement in the 2nd if statement, **MITCHELL CHAN R7Y9A**

SANDRA YOO A9X9A

$$x_{\text{new}} = x_{\text{old}}$$

$\text{Product}_{\text{new}} = \text{Product}_{\text{old}} + x_{\text{old}}$, and after execution of the 2nd statement in the 2nd if statement,

$$y_{\text{new}} = y_{\text{old}} - 1$$

$$y_{\text{new}} = (2q+1) - 1 \quad (\text{substitution from above})$$

$$y_{\text{new}} = 2q \quad (\text{Note: in our case, } 2q \text{ is } <)$$

We now get

$$x_{\text{new}}y_{\text{new}} + \text{Product}_{\text{new}} = x_{\text{old}}2q + \text{product}_{\text{old}} + x_{\text{old}} = x_{\text{old}}2q + x_{\text{old}} + \text{product}_{\text{old}}$$

We factor out the x_{old} and we get

$$= x_{\text{old}}(2q+1) + \text{product}_{\text{old}} \quad (x_{\text{old}}(k+2) + \text{product}_{\text{old}})$$

$$= x_{\text{old}}y_{\text{old}} + \text{product}_{\text{old}}$$

$$= AB$$

Hence, $I(k+1)$ is true.

III. Eventual Falsity of Guard (after a finite number of iterations of the loop, G becomes false)

The guard G is the condition $y \neq 0$. By I and II it is known that for all $y > 0$, the loop is iterated then $xy + \text{product} = AB$. Each value of y obtained by repeated iteration will reach a least value, y_{\min} . When $y_{\min} = 0$, the guard G is false.

IV. Correctness of the post-condition (If N is the least number of iterations after which G is false and $I(N)$ is true, then the values of the algorithm variables will be as specified in the post condition)

Suppose that for some non-negative integer N , G is false and $I(N)$ is true.

Since G is false, $y = 0$, and since $I(N)$ is true,

$$\begin{aligned} x(0) + \text{product} &= AxB \\ 0 + \text{product} &= AxB \Rightarrow \text{product} = AB \end{aligned}$$

RESOURCES USED: Discrete Mathematics with Applications by Susanna EPP (used to follow the structure of loop invariant theorem, used similar structure and style and wording to examples on P. 282-287)

#11 Theorem: A ternary tree of height h has at most

$$\frac{3^{h+1}-1}{2} \text{ nodes.}$$

**MITCHELL CHAN R7Y9A
SANDRA YOO A9X9A**

PROOF

We will use proof by induction.
we know if the height of the ternary tree is h , we can say the maximum number of nodes in a ternary tree is

$$3^0 + 3^1 + 3^2 + \dots + 3^h = \sum_{i=0}^h 3^i = \frac{3^{h+1}-1}{2}$$

Base cases: when $h = -1$, it is an empty tree (as stated in the question)

when $h = 0$, we get

$3^0 = 1$ for the LHS, and

$\frac{3^{0+1}-1}{2} = 1$ for the RHS. Since $LHS = RHS$, the theorem

holds for $h = 0$.

Induction hypothesis

We assume that the theorem holds for $h = k$,

$$3^0 + 3^1 + 3^2 + \dots + 3^k = \frac{3^{k+1}-1}{2}, \text{ so let us prove this for } h = k+1.$$

If we add 3^{k+1} , by the induction hypothesis we get

$$\begin{aligned} 3^0 + 3^1 + 3^2 + \dots + 3^k + 3^{k+1} &= \frac{3^{k+1}-1}{2} + 3^{k+1} \\ &= \frac{3^{k+1}-1 + 2 \cdot 3^{k+1}}{2} = \frac{9^{k+1}-1}{2} = \frac{3 \cdot 3^{k+1}-1}{2} \\ &= \frac{3^{(k+1)+1}-1}{2} \end{aligned}$$

Thus, the theorem holds for $h = k+1$, and we are done. QED.
